

Features

10/100/1000 Ethernet in one instrument

With 10/100/1000 Base-T and SX/LX Gigabit support in one interface module, the DA-3400 and DA-3600A each provide an all-in-one test tool for Ethernet troubleshooting. Network connections may be through Ethernet switch SPAN ports, network TAPs, or in-line monitoring.

VoIP analysis option

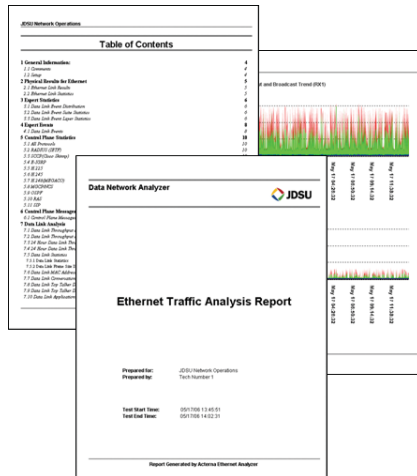

Accurate at full line rate, the VoIP analysis option for the DA-3400 and DA-3600A provides detailed quality statistics and signaling message exchanges. The patented problem segmentation feature reduces the time it takes to locate the source of VoIP problems.

Combined VoIP and data analysis

The Ethernet Analysis Software performs VoIP and data analysis simultaneously. Technicians can quickly identify issues of resource contention, conflicting priority settings, and a wide variety of other problems that can result in poor network performance and dissatisfied users.

Event identification and notification

Fully integrated expert analysis software identifies and notifies technicians of events through all seven protocol layers. Automated e-mail notification and SNMP trap generation are independently configurable for each network event. Additionally, expert events can be utilized to automatically generate capture files for later analysis.

Reporting

Professional customizable reports can be created quickly and easily. The output format can be fully formatted for printing. In addition, the output format is compatible for use with database applications.

Control plane analysis

The Ethernet Analysis Software provides a view for control plane protocols that are related to routing, signaling, and authentication. Protocols statistics and display filters allow technicians to focus on specific message exchanges. Full decodes are available in real time for any control plane protocol.

VLAN, subnet, and MPLS analysis

The Ethernet Analysis Software automatically classifies traffic by its VLAN, subnet, or MPLS label. These classifications provide technicians with the ability to quickly identify bandwidth consumption, application distribution, and other relevant parameters within these traffic groupings.

Application response time measurement

The application response time option provides details of DNS lookup time, client-to-server network latency, and server response time, along with details on MTU, retransmissions, and other transport parameters. This allows technicians to quickly identify specific problem areas that are the source of poor network and application response times.

History mode

The test instrument's History mode allows technicians to view network traffic, applications, station statistics, and events for set periods of time. Defining the time period is accomplished using a graphical window that is integrated with a network utilization graph.

Remote or local operation

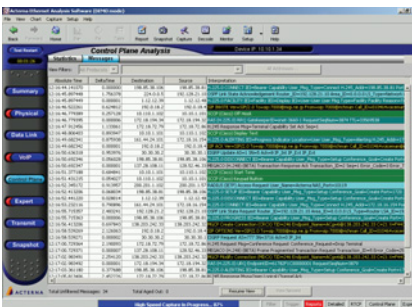

Using IP networks or dial-up connections, technicians can control the DA-3400 or DA-3600A remotely. For portable applications, a direct PC connection is also supported. Once initiated, network monitoring continues without the need to maintain the connection.

Real-time decodes

Protocol decodes, including summary, detailed, and hex displays, are displayed in real time. Packets streamed to the technician's PC can be saved onto a disk for subsequent analysis. Full filtering is supported, displaying only the frames of interest.

Tunneling support

Support for tunneled traffic allows technicians to monitor the tunnels or the traffic within the tunnels.

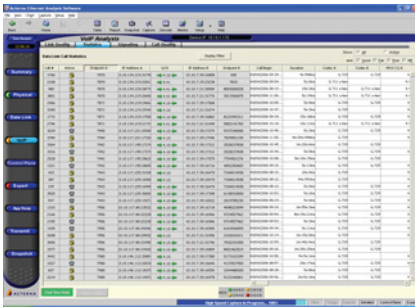

Applications

VoIP quality analysis

Monitoring and troubleshooting quality problems on VoIP networks presents a unique set of issues. The VoIP Analysis option for the Ethernet Analysis Software provides technicians with displays of overall call load, multiple call statistics, and single call details. This allows technicians to evaluate the overall VoIP quality, identify trends, and troubleshoot single call related issues. Expert events detail problems and reduce the time it takes to resolve issues.

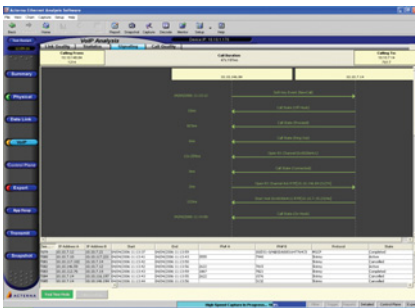

VoIP monitoring is performed using custom hardware to ensure absolutely accurate statistics, including jitter, packet loss, and MOS, on fully utilized Ethernet circuits with up to Gigabit speeds.

Call ID	Source IP	Destination IP	Start Time	End Time	Duration	Call Type	Quality	Events
1001	192.168.1.10	192.168.1.20	10/10/2010 10:00:00	10/10/2010 10:05:00	00:05:00	Normal	Good	Call Setup, Call Teardown
1002	192.168.1.15	192.168.1.25	10/10/2010 10:01:00	10/10/2010 10:06:00	00:05:00	Normal	Good	Call Setup, Call Teardown
1003	192.168.1.20	192.168.1.30	10/10/2010 10:02:00	10/10/2010 10:07:00	00:05:00	Normal	Good	Call Setup, Call Teardown
1004	192.168.1.25	192.168.1.35	10/10/2010 10:03:00	10/10/2010 10:08:00	00:05:00	Normal	Good	Call Setup, Call Teardown
1005	192.168.1.30	192.168.1.40	10/10/2010 10:04:00	10/10/2010 10:09:00	00:05:00	Normal	Good	Call Setup, Call Teardown

VoIP signaling analysis

Troubleshooting VoIP signaling can be time consuming. The VoIP Analysis option provides a display of signaling message exchanges for individual calls. This display includes information on timing and result codes, allowing technicians to identify problems quickly.

Message ID	Direction	Message Type	Source IP	Destination IP	Timestamp	Status
1	Outgoing	INVITE	192.168.1.10	192.168.1.20	10/10/2010 10:00:00	Success
2	Incoming	200 OK	192.168.1.20	192.168.1.10	10/10/2010 10:00:05	Success
3	Outgoing	BYE	192.168.1.10	192.168.1.20	10/10/2010 10:05:00	Success
4	Incoming	200 OK	192.168.1.20	192.168.1.10	10/10/2010 10:05:05	Success

Quality of service monitoring

VLAN priorities and IP DiffServ code points are used to set the quality of service (QoS) levels for different types of traffic. The Ethernet Analysis Software displays the QoS settings for all data and VoIP connections on the network, allowing technicians to quickly identify and resolve configuration issues related to the QoS parameter settings.

Control plane analysis

Routing, signaling, and authentication protocols are used to define routing paths and validate users. Problems with packet exchanges can result in poor network performance, connection failures, and other issues.

The Control Plane Analysis feature supports real-time monitoring of RIP, BGP, OSPF, RSVP, EIGRP, LDP/TE, SigTran, IGMP, RADIUS, H.323, SIP, MEGACO/H.248, CiscoSCCP, and MGCP/NCS.

5

Application response analysis

Slow network response time is a common user complaint. Network latency, DNS lookup time, server request processing time, MTU size, and other factors directly impact the user experience and their perception of network performance. The Application Response Time option quickly identifies problems with the application design, client/server configuration, router configuration, or network packet transport. This allows technicians to optimize applications and quickly determine if problems are within the network, the client/server equipment, or the application.

Security analysis

Computers that become compromised by worms or virus can inflict damage on the network. The Ethernet Analysis Software can monitor for hosts generating traffic profiles that indicate a compromised host. JDSU makes available, via the Internet, a variety of different filter files that are designed to identify traffic patterns generated by specific worms and viruses.

Network baselining

Baselining is the process of monitoring long-term trends, applications, and user patterns for the purpose of profiling the network. This information can then be used as a reference to ensure that new applications can be supported, identify the impact of new applications, isolate problems, and generate general performance overviews. The Ethernet Analysis Software provides long-term monitoring and reporting capabilities that are specifically designed to provide technicians with this valuable information.

Filter, capture, and decode

With its one Gigabit capture buffer, the DA-3400 and DA-3600A can capture and decode millions of frames. To reduce the amount of traffic that must be analyzed, the Ethernet analysis hardware filters are designed to be the most powerful in the industry. Multiple filters can be defined based on parameters such as VLANs, IP addresses, or subnets. More specific parameters, such as DiffServ code points or IP options, are also available. Pattern match filters identify packets containing specific data strings. Technicians can be assured that the captured traffic contains only those packets that match the filter settings.
